

## Analysis of Algorithms CS 3343 Lecture Ten

Prof. William Winsborough  
October 23, 2008

## Business

- Turn in Homework 5
  - Problem 7.1 (p.159)
  - Recall, I will also accept it Tuesday, 10/28.
- Recall Reading: 7.1, 7.2, 5.1, 5.2, 7.3, 7.4
- Homework 6: 5.2-3, 5.2-4, 7.2-1, 7.2-4, 7.3-1, 7.3-2, 7.4-1
  - Also: Justify each inequality in the derivation of A.10 on p.1066
  - And: explain the relationship between A.10 and the Norman Conquest (just kidding)

2

## Quicksort Algorithm

- Partition(A, p, r)
  1.  $x \leftarrow A[r]$
  2.  $i \leftarrow p - 1$
  3. for  $j \leftarrow p$  to  $r - 1$
  4.     do if  $A[j] \leq x$
  5.         then  $i \leftarrow i + 1$
  6.             exchange  $A[i] \leftrightarrow A[j]$
  7. exchange  $A[i + 1] \leftrightarrow A[r]$
  8. return  $i + 1$

Winsborough CS 3343 Lecture 10

3

## Randomized Quicksort

- What does randomizing achieve?
- Refer to algorithm on p.154

23 October 2008

Winsborough CS 3343 Lecture 10

4

## Worst-case Analysis of Quicksort

- Refer to the proof on p.155 that the worst-case running time is  $\Theta(n^2)$

23 October 2008

5

## Expected-case Running time of Quicksort: Intuition Reprise

- We will assume the values in the input are distinct from one another
  - Why?
- We saw last time that if the splits created by partition are proportional to a constant (like 9 to 1), then the running time remains  $\Theta(n \lg n)$
- The book also shows that if you introduce a couple really unbalanced splits between proportional splits, running time still remains  $\Theta(n \lg n)$

23 October 2008

Winsborough CS 3343 Lecture 10

6

## Expected-case Formal Analysis

- There are at most  $n$  calls to Partition
  - This is because the pivot is always removed before making recursive calls to quicksort
- If  $X$  is the number of comparisons performed in line 4 throughout the entire execution of quicksort, then the running time is  $O(n + X)$
- So our goal is to compute the expected value of  $X$

23 October 2008

7

## Expected-case Formal Analysis, Cont.

- We analyze the total comparisons made during the *entire* computation, not just in one call to partition
- Need to understand when two elements of the array are compared and when they are not
- Let  $z_1, z_2, \dots, z_n$  enumerate the elements of the array from smallest to biggest
  - Let  $Z_{i,j} = \{z_i, z_{i+1}, \dots, z_j\}$
- When does the algorithm compare  $z_i$  and  $z_j$ ?
- Note that each pair of elements is compared at most once
  - Elements are compared only to the pivot, and once a value is used as a pivot, it is never again compared to any element

23 October 2008

Winsborough CS 3343 Lecture 10

8

## Expected-case Formal Analysis, Cont.

- Let  $X_{i,j} = I\{z_i \text{ is compared to } z_j\}$ 
  - Indicator random variable as discussed on Tuesday (sec. 5.2)
- $X = \sum_{1 \leq i \leq n-1} \sum_{i+1 \leq j \leq n} X_{i,j}$
- $$\begin{aligned} E[X] &= E\left[\sum_{1 \leq i \leq n-1} \sum_{i+1 \leq j \leq n} X_{i,j}\right] \\ &= \sum_{1 \leq i \leq n-1} \sum_{i+1 \leq j \leq n} E[X_{i,j}] \\ &= \sum_{1 \leq i \leq n-1} \sum_{i+1 \leq j \leq n} \Pr\{z_i \text{ is compared to } z_j\} \end{aligned}$$
- Remains to compute  $\Pr\{z_i \text{ is compared to } z_j\}$

23 October 2008

Winsborough CS 3343 Lecture 10

9

## Expected-case Formal Analysis, Cont.

- When are two elements not compared?
  - Suppose values 1..10 (in any order) are to be partitioned
  - If 7 is selected as the pivot, the numbers 1..6 will never be compared with the numbers 8..10
  - In general, if  $z_i < x < z_j$ , and  $x$  is chosen as a pivot,  $z_i$  and  $z_j$  will never be compared later
- On the other hand, if  $z_i$  is chosen as a pivot, it will be compared to each element of  $Z_{i+1,j}$ 
  - Similarly if  $z_j$  is chosen
  - In the example, 7 and 9 are compared, because 7 is the first item from  $Z_{7,9}$  to be chosen as a pivot
  - On the other hand, 2 and 9 are not compared because the first item from  $Z_{2,9}$  chosen as a pivot is 7

23 October 2008

Winsborough CS 3343 Lecture 10

10

## Expected-case Formal Analysis, Cont.

- In general,  $z_i$  and  $z_j$  will be compared just in case one of them is the first pivot chosen from  $Z_{i,j}$
- Recall:
  - The probability of any item being chosen as a pivot is the same as the probability of any other element being chosen
  - There are  $j-i+1$  elements in  $Z_{i,j}$
  - So the probability of  $z_i$  being chosen before any other element in  $Z_{i,j}$  is  $1/(j-i+1)$
  - Likewise for  $z_j$

23 October 2008

Winsborough CS 3343 Lecture 10

11

## Expected-case Formal Analysis, Cont.

- So,
 
$$\begin{aligned} \Pr\{z_i \text{ is compared to } z_j\} &= \Pr\{z_i \text{ or } z_j \text{ is the first pivot chosen from } Z_{i,j}\} \\ &= \Pr\{z_i \text{ is the first pivot chosen from } Z_{i,j}\} \\ &\quad + \Pr\{z_j \text{ is the first pivot chosen from } Z_{i,j}\} \\ &\quad (\text{because the two events are mutually exclusive}) \\ &= 1/(j-i+1) + 1/(j-i+1) \\ &= 2/(j-i+1) \end{aligned}$$
- Now refer to equation 7.4 on p.158
