Background information about Critical Path Analysis from a textbook: A critical path analysis is a technique used to determine the time schedule for a project. This information is important in the planning stages before a project is begun, and it is also useful to evaluate the progress of a project that is partially completed. One method for this analysis starts by dividing a project into sequential events and then dividing each event into various tasks. Although one event must be completed before the next one is started, various tasks within an event can occur simultaneously. The time it takes to complete an event, therefore, depends on the number of days required to finish its longest task. Similarly, the total time it takes to finish a project is the sum of time it takes to finish each event.

Assume that the critical path information for a major construction project has been stored in a data file. Each line of the data file contains an event number, a task number, and the number of days required to complete the task. The data have been stored such that all the task data for the first event are followed by all the task data for the second event, and so on. A typical set of data is shown in the following table.

Event	Task	Number of Days
-------	------	----------------

1	15	3
1	27	6
1	36	4
2	15	5
3	18	4
3	26	1
4	15	2
4	26	7
4	27	7
5	16	4

You can simply download critical1.txt from the web page or simply open a file critical1.txt and copy/paste just the above numbers into that file.

Programming problem:

Write a program that gets two file names as command line arguments after -input and -output options, for example

```
main212> myprog -input critical1.txt -output output1.txt
or
main212> myprog -output output1.txt -input critical1.txt
```

If user enters less arguments or invalid options, your program should print the above usage information and quit.

Then your program reads the critical path information from critical1.txt file and prints a project completion timetable into output1.txt. Timetable lists each event number, number of tasks under this event, the maximum number of days for this event, and the total number of days for the project completion.

For example, your output1.txt will look like as follows based on the above input file:

Project completion timetable				
Event	Num of tasks	Max num.of days		
1	3	6		
2	1	5		
3	2	4		
4	3	7		
5	1	4		

Total number of days to finish the project: 26 days

Note that we might give different input file so your program should be general enough to produce correct result for any input file!

You must submit your work using Blackboard Learn and respect the following rules:

- 1) All assignments must be submitted as either a zip or tar archive file unless it is a single pdf file.
- 2) Assignments must include all source code.
- 3) Assignments must include an output.txt file which demonstrates the final test output run by the student.
- 4) If your assignment does not run/compile, the output.txt file should include an explanation of what was accomplished, what the error message was that prevented the student from finishing the assignment and what the student BELIEVES to be the underlying cause of the error.
